

When running the code:

```
int main(int argc, char** argv) {  
    for (;;) system(argv[0]);  
}
```

It was observed that the program just seemed to hang at the command line, however, the RAM usage indicator in the taskbar in the Linux distro showed that RAM usage was steadily increasing while the program was running. This program likely creates a bunch of processes and doesn't clear their memory usage so it will just continue and deprive the system of RAM. A potential way that this could be protected against is having some type of program that monitors for unchecked process creation and stopping the offending programs.
